

25 March 2022

§ 9(2)(a)

By email: § 9(2)(a)  
Ref: H202204097

Dear § 9(2)(a)

### Response to your request for official information

Thank you for your request under the Official Information Act 1982 (the Act) to the Ministry of Health (the Ministry) on 23 February 2022 for:

*"I am looking for a datasheet for Xtandi."*

Please find the most recent data sheet for *XTANDI® (enzalutamide)* that Medsafe holds on file attached to this letter as Document 1. This document has been released to you in full.

I trust this information fulfils your request. Under section 28(3) of the Act, you have the right to ask the Ombudsman to review any decisions made under this request. The Ombudsman may be contacted by email at: [info@ombudsman.parliament.nz](mailto:info@ombudsman.parliament.nz) or by calling 0800 802 602.

Please note that this response, with your personal details removed, may be published on the Ministry website at: [www.health.govt.nz/about-ministry/information-releases/responses-official-information-act-requests](http://www.health.govt.nz/about-ministry/information-releases/responses-official-information-act-requests).

Yours sincerely,

Derek Fitzgerald  
**(Acting) Group Manager**  
**Medsafe**

## New Zealand Data Sheet

### XTANDI® (enzalutamide) 40 mg Soft Capsules

#### Presentation

XTANDI capsules are presented as white to off-white oblong soft gelatin capsules imprinted with “ENZ” in black ink on one side.

Each capsule contains 40 mg enzalutamide as the active ingredient.

#### Indications

XTANDI is indicated for:

- the treatment of patients with metastatic castration resistant prostate cancer following failure of androgen deprivation therapy in whom chemotherapy is not yet indicated.
- the treatment of patients with metastatic castration-resistant prostate cancer who have previously received docetaxel.

#### Dosage and Administration

The recommended dose of XTANDI is 160 mg (four 40 mg capsules) as a single oral daily dose. Swallow capsules whole with water. Do not chew, dissolve, or open the capsules.

XTANDI can be taken with or without food.

If a patient experiences a  $\geq$  Grade 3 toxicity or an intolerable adverse reaction, withhold dosing for one week or until symptoms improve to  $\leq$  Grade 2, then resume at the same or a reduced dose (120 mg or 80 mg) if warranted.

#### Concomitant Use with Strong CYP2C8 Inhibitors

The concomitant use of strong CYP2C8 inhibitors should be avoided if possible. If patients must be co-administered a strong CYP2C8 inhibitor, reduce the dose of XTANDI to 80 mg once daily. If co-administration of the strong CYP2C8 inhibitor is discontinued, the XTANDI dose should be returned to the dose used prior to initiation of the strong CYP2C8 inhibitor (see **Interactions**).

#### Patients with Hepatic Impairment

No dose adjustment is required for patients with mild, moderate or severe hepatic impairment (Child-Pugh Class A, B or C respectively).

#### Patients with Renal Impairment

No dose adjustment is necessary for patients with mild or moderate renal impairment (see **Further Information**: Pharmacokinetics: Pharmacokinetic characteristics in special populations). Caution is advised in patients with severe renal impairment or end-stage renal disease (see **Warnings and Precautions**: Renal Impairment).

### Elderly

No dose adjustment is required for the elderly.

### Paediatrics

XTANDI is not recommended for use in children.

### **Contraindications**

XTANDI is contraindicated in patients with known hypersensitivity to enzalutamide or to any of the excipients in the formulation (see **Further Information: Other: List of Excipients**).

XTANDI is not indicated for use in women. XTANDI is contraindicated in women who are, or may become, pregnant (see **Warnings and Precautions: Use in Pregnancy**).

### **Warnings and Precautions**

XTANDI capsules should only be prescribed by a medical practitioner who is experienced with the treatment of prostate cancer and the use of antineoplastic endocrine therapies.

The following are clinically significant: seizures (see Risk of Seizure below), PRES (see Posterior Reversible Encephalopathy Syndrome below) and drug interactions (see **Interactions**).

### Risk of Seizure

The risk to patients, especially those with predisposing factors for seizures has not been studied and is unknown. In the AFFIRM clinical trial, which enrolled patients who previously received docetaxel, 7 of 800 (0.9%) patients treated with XTANDI 160 mg once daily experienced a seizure. No seizures occurred in patients treated with placebo. In the PREVAIL clinical trial, 1 of 871 (0.1%) chemotherapy-naïve patients treated with XTANDI and 1 of 844 (0.1%) patients treated with placebo experienced a seizure. Patients experiencing a seizure were permanently discontinued from therapy and all seizure events resolved. There is no clinical trial experience re-administering XTANDI to patients who experienced seizure.

Because of the risk of seizure associated with XTANDI use, patients should be advised of the risk of engaging in any activity where sudden loss of consciousness could cause serious harm to themselves or others.

Caution should be used in administering XTANDI to patients with a history of seizures or other predisposing factors including, but not limited to, underlying brain injury, stroke, primary brain tumours or brain metastases, or alcoholism. In addition, the risk of seizure may be increased in patients receiving concomitant medicines that lower the seizure threshold.

### Posterior Reversible Encephalopathy Syndrome

There have been rare reports of posterior reversible encephalopathy syndrome (PRES) in patients receiving XTANDI. PRES is a rare, reversible, neurological disorder which can present with rapidly evolving symptoms including seizure, headache, confusion, blindness, and other visual and neurological disturbances, with or without associated hypertension. A diagnosis of PRES requires confirmation by brain imaging, preferably magnetic resonance imaging (MRI). Discontinuation of XTANDI in patients who develop PRES is recommended.

### Falls and Fall-Related Injuries

In the two randomised clinical trials (AFFRIM and PREVAIL), falls or injuries related to falls occurred in 9% of patients treated with XTANDI compared to 4% of patients treated with placebo. Falls were not associated with loss of consciousness or seizure. Fall-related injuries were more severe in patients treated with XTANDI and included non-pathologic fractures, joint injuries, and hematomas. Androgen deprivation therapy has been known to cause bone loss. For patients who fall or have a concomitant recognised risk of falling, it is recommended that the physicians consider additional supportive therapy when appropriate.

### Hypersensitivity Reactions

Hypersensitivity reactions manifested by symptoms including, but not limited to, tongue oedema, lip oedema and pharyngeal oedema have been observed with enzalutamide (see **Contraindications**).

### Androgen Deprivation Therapy May Prolong the QT Interval

In patients with a history of or risk factors for QT prolongation and in patients receiving concomitant medicinal products that might prolong the QT interval, physicians should assess the benefit risk ratio including the potential for Torsade de pointes prior to initiating XTANDI.

### Recent Cardiovascular Disease

The phase 3 studies excluded patients with recent myocardial infarction (in the past 6 months) or unstable angina (in the past 3 months), New York Heart Association (NYHA) Class III or IV heart failure except if Left Ventricular Ejection Fraction (LVEF)  $\geq$  45%, bradycardia or uncontrolled hypertension. This should be taken into account if XTANDI is prescribed in these patients.

### Hypertension

In the two randomized trials, hypertension was reported in 11% of patients receiving XTANDI and 4% of patients receiving placebo. The difference in frequency of hypertensive events between the enzalutamide and placebo-treated groups was larger in the PREVAIL trial (13.9% enzalutamide; 4.7% placebo) than in the AFFIRM trial (7% enzalutamide; 3.2% placebo). No patients experienced hypertensive crisis. Medical

history of hypertension was balanced between arms. Hypertension led to study discontinuation in <1% of patients in each arm.

### Risk of Second Malignancy

In the PREVAIL study, the event rate of second malignancy was higher in the enzalutamide arm (1.9 events per 100 patient-years; median follow-up time was 17.1 months) than the placebo arm (0.7 events per 100 patient-years; median follow-up time was 5.4 months). Median time to onset of second malignancy, excluding non-melanoma skin cancer, was 267 days (range 8 to 856 days) in the enzalutamide group and 229 days (range 15 to 454 days) in the placebo group.

### Use with Chemotherapy

The safety and efficacy of concomitant use of XTANDI with cytotoxic chemotherapy has not been established.

### Renal Impairment

Caution is required in patients with severe renal impairment as XTANDI has not been studied in this patient population.

### Contraception in Males and Females

As it is not known whether XTANDI or its metabolites are present in semen and there were severe teratogenic effects observed in the animal studies, a condom is required during and for 3 months after treatment with XTANDI if the patient is engaged in sexual activity with a pregnant woman. If the patient engages in sexual intercourse with a woman of childbearing potential, a condom and another form of birth control must be used during and for 3 months after treatment. Studies in animals have shown reproductive toxicity (see **Warnings and Precautions: Effects on fertility**).

### Effects on Fertility

Based on its pharmacology and findings in animal studies, male fertility may be impaired by treatment with enzalutamide. Findings in the male reproductive tract of rats and/or dogs treated with enzalutamide included atrophy of the prostate gland and seminal vesicles, testicular hypospermia and seminiferous tubule degeneration. These effects were observed at all dose levels (below the clinical exposure based on AUC) and reversed or partially resolved after an 8-week recovery period.

### Use in Pregnancy (Category X)

*Category X - Drugs which have such a high risk of causing permanent damage to the fetus that they should not be used in pregnancy or when there is a possibility of pregnancy.*

XTANDI is not for use in women. XTANDI has not been shown to be safe for use in women. XTANDI is contraindicated in women who are or may become pregnant (see **Contraindications**). There are no human data on the use of XTANDI in pregnancy.

Teratogenicity (cleft palate, cervical rib and decreased anogenital distance) and embryofetal lethality were seen in mouse embryofetal development studies at greater than or equal to 10 mg/kg/day (below the clinical exposure based on AUC).

#### Use in Lactation

XTANDI is not indicated for use in women and has not been shown to be safe in children. It is not known whether XTANDI is secreted in human milk.

#### Paediatric Use

The safety of XTANDI has not been studied in children, and therefore it is not recommended for use in those <18 years of age.

#### Use in the Elderly

No clinically relevant effect of age on XTANDI pharmacokinetics was seen in the population pharmacokinetic analysis. No dose adjustment is required for the elderly.

#### Effect on Laboratory Tests

There is no information on the effect of enzalutamide on laboratory tests.

#### Effects on Ability to Drive and Use Machines

Neurological and psychiatric events have occurred in patients taking XTANDI (see **Adverse Effects**). No formal studies of the effects of XTANDI on the ability to drive or use machines have been conducted. Patients with a history of seizures or other predisposing factors (see **Warnings and Precautions: Risk of Seizure and Interactions**) should be advised of the risk of driving or operating machines.

#### Genotoxicity

Enzalutamide did not induce mutations in the microbial mutagenesis (Ames) assay and was not clastogenic in either the *in vitro* cytogenetic assay with mouse lymphoma cells or the *in vivo* mouse micronucleus assay.

#### Carcinogenicity

Long-term animal studies to evaluate the carcinogenic potential of enzalutamide have not been conducted.

### **Adverse Effects**

#### Clinical Trial Experience

The most common adverse reactions ( $\geq 10\%$ ) that occurred more commonly ( $\geq 2\%$  over placebo) in the XTANDI-treated patients reported in the two randomized clinical trials were asthenia/fatigue, back pain, decreased appetite, constipation, arthralgia, diarrhoea, hot flush, and upper respiratory tract infection, peripheral oedema, dyspnoea, musculoskeletal pain, weight decreased, headache, hypertension, and

dizziness/vertigo. All adverse events and laboratory abnormalities were graded using NCI CTCAE version 4.

### Study 1: Metastatic Castration-Resistant Prostate Cancer Following Chemotherapy (AFFIRM)

Study 1 (AFFIRM) enrolled 1199 patients with metastatic castration-resistant prostate cancer (CRPC) who had previously received docetaxel. The median duration of treatment was 8.3 months with XTANDI and 3.0 months with placebo. During the trial, 48% of patients on the XTANDI arm and 46% of patients on the placebo arm received glucocorticoids.

Grade 3 and higher adverse reactions were reported among 47% of XTANDI-treated patients and 53% of placebo-treated patients. Discontinuations due to adverse events were reported for 16% of XTANDI-treated patients and 18% of placebo-treated patients. The most common adverse reaction leading to treatment discontinuation was seizure, which occurred in 0.9% of the XTANDI-treated patients compared to none (0%) of the placebo-treated patients. Table 1 shows adverse reactions reported in the randomised clinical trial that occurred at a  $\geq 2\%$  absolute increase in frequency in the XTANDI arm compared to the placebo arm.

**Table 1. Adverse Reactions in Study 1 (AFFIRM)**

	XTANDI N = 800		Placebo N = 399	
	Grade 1-4 (%)	Grade 3-4 (%)	Grade 1-4 (%)	Grade 3-4 (%)
<b>General Disorders</b>

a Includes asthenia and fatigue. b Includes dizziness and vertigo. c Includes amnesia, memory impairment, cognitive disorder, and disturbance in attention. d Includes nasopharyngitis, upper respiratory tract infection, sinusitis, rhinitis, pharyngitis, and laryngitis. e Includes pneumonia, lower respiratory tract infection, bronchitis, and lung infection.				

### Study 2: Chemotherapy-naive Metastatic Prostate Cancer that Progressed on Androgen Deprivation Therapy (PREVAIL)

Study 2 (PREVAIL) enrolled 1717 patients with metastatic prostate cancer that progressed on an LHRH analogue or after bilateral orchiectomy and had not received prior cytotoxic chemotherapy, of whom 1715 received at least one dose of study drug. The median duration of treatment was 16.6 months with XTANDI and 4.6 months with placebo. The most common adverse reaction leading to treatment discontinuation was fatigue, which occurred in 0.2% of the XTANDI-treated patients compared to 0.9% of placebo-treated patients.

Table 2 includes adverse reactions reported in Study 2 that occurred at a  $\geq 2\%$  absolute increase in frequency in the XTANDI arm compared to the placebo arm.

Table 2. Adverse Reactions in Study 2 (PREVAIL)

Gynecomastia	3.4	0.0	1.4	0.0
a Includes asthenia and fatigue. b Includes dizziness and vertigo. c Includes amnesia, memory impairment, cognitive disorder, and disturbance in attention. d Includes dyspnoea, exertional dyspnoea, and dyspnoea at rest. e Includes nasopharyngitis, upper respiratory tract infection, sinusitis, rhinitis, pharyngitis, and laryngitis. f Includes pneumonia, lower respiratory tract infection, bronchitis, and lung infection.				

The following additional adverse reactions were reported during the two randomised trials and are listed by frequency category. Frequency categories are defined as follows: very common reactions are defined as those occurring in  $\geq 10\%$  of patients, common reactions are defined as those occurring in  $\geq 1\%$  and  $< 10\%$  of patients, uncommon reactions are defined as those occurring in  $\geq 0.1\%$  and  $< 1\%$  of patients, and rare reactions are defined as those occurring in  $< 0.1\%$  of patients.

### Blood and lymphatic system disorders

Uncommon: leukopenia, neutropenia

### General disorders

Very common: asthenia/fatigue

### Psychiatric disorders

Common: anxiety

Uncommon: visual hallucinations

### Nervous system disorders

Uncommon: seizure

Common: restless legs syndrome, amnesia

Reproductive system and breast disorder

Common: gynaecomastia

### Post Marketing Experience:

The following adverse events, which are not listed above, have been reported in association with enzalutamide use during worldwide post-marketing experience:

*Musculoskeletal and connective tissue disorders:* myalgia, muscle spasms, muscular weakness, back pain

*Nervous system disorders:* Posterior Reversible Encephalopathy Syndrome (see **Warnings and Precautions**)

## Description of Selected Adverse Reactions

### *Seizures*

In the phase 3 clinical studies, 8 patients (0.5%) experienced a seizure out of 1671 patients treated with a daily dose of 160 mg enzalutamide, whereas one patient (<0.1%) receiving placebo experienced a seizure. . Patients who are taking concomitant medicines (strong CYP2C8 inhibitors) that increase the blood levels of enzalutamide may be at increased risk of seizure (See **Warnings and Precautions** and **Interactions**).

In the AFFIRM trial, 7 of 800 (0.9%) post-chemotherapy patients treated with XTANDI 160 mg once daily experienced a seizure. Seizures occurred from 31 to 603 days after initiation of XTANDI. No seizures occurred in patients treated with placebo. In the PREVAIL trial, 1 of 871 (0.1%) chemotherapy naïve patients treated with XTANDI 160 mg once daily, and 1 of 844 (0.1%) patients treated with placebo experienced a seizure events resolved. There is no clinical trial experience re-administering XTANDI to patients who experienced seizure. Seizure reactions identified during the post-marketing experience based on spontaneous reports with XTANDI demonstrate a frequency of  $\geq 0.1\%$  and  $< 1\%$  (Uncommon).

### *Laboratory abnormalities*

In the two randomised clinical trials (AFFIRM and PREVAIL), Grade 1-4 neutropenia occurred in 14% of patients treated with XTANDI (1% Grade 3-4) and in 6% of patients treated with placebo (0.5% Grade 3-4). The incidence of Grade 1-4 thrombocytopenia was 6% of patients treated with XTANDI (0.3% Grade 3-4) and 5% of patients on placebo (0.5% Grade 3-4). Grade 1-4 elevations in ALT occurred in 10% of patients treated with XTANDI (0.2% Grade 3-4) and 16% of patients treated with placebo experienced (0.2% Grade 3-4). Grade 1-4 elevations in bilirubin occurred in 3% of patients treated with XTANDI (0.1% Grade 3-4) and 2% of patients treated with placebo.

### *Infections*

In the AFFIRM trial, 1% of patients treated with XTANDI compared to 0.3% of patients on placebo died from infections or sepsis. In the PREVAIL trial, 1 patient in each treatment group (0.1%) had an infection resulting in death.

### *Hallucinations*

In the AFFIRM trial, 1.6% of patients treated with XTANDI were reported to have Grade 1 or 2 hallucinations compared to 0.3% of patients on placebo. In the PREVAIL trial, 1 patient in each treatment group (0.1%) reported an event of Grade 1 hallucination. Of the patients with hallucinations, the majority were on opioid-containing medications at the time of the event. Hallucinations were visual, tactile, or undefined.

## Interactions

### Effects of other Medicines on XTANDI

#### *CYP2C8 Inhibitors*

CYP2C8 plays an important role in the elimination of enzalutamide and in the formation of its active metabolite. Following oral administration of the strong CYP2C8 inhibitor gemfibrozil (600 mg twice daily) to healthy male subjects, the AUC of the sum of enzalutamide plus the active metabolite increased by 2.17-fold while  $C_{max}$  decreased by 16%. Strong inhibitors (e.g. gemfibrozil) CYP2C8 are to be avoided or used with caution during enzalutamide treatment. If patients must be co-administered a strong CYP2C8 inhibitor, the dose of enzalutamide should be reduced to 80 mg once daily (see **Dosage and Administration**).

#### *CYP3A4 Inhibitors*

CYP3A4 plays a minor role in the metabolism of enzalutamide. Following oral administration of the strong CYP3A4 inhibitor itraconazole (200 mg once daily) to healthy male subjects, the AUC of enzalutamide increased by 41% while  $C_{max}$  was unchanged. For the sum of unbound enzalutamide plus the unbound active metabolite, the AUC increased by 27% while  $C_{max}$  was again unchanged. No dose adjustment is necessary when enzalutamide is co-administered with inhibitors of CYP3A4.

#### *CYP2C8 and CYP3A4 inducers*

In a drug-drug interaction trial in healthy volunteers, a single 160 mg oral dose of enzalutamide was administered alone or after multiple oral doses of rifampicin (moderate CYP2C8 and strong CYP3A4 inducer). Rifampicin decreased the AUC<sub>0-inf</sub> of enzalutamide plus N-desmethyl enzalutamide by 37% with no effect on  $C_{max}$ .

### Effects of XTANDI on other Medicines

#### *Enzyme induction*

Enzalutamide is a potent enzyme inducer and increases the synthesis of many enzymes and transporters; therefore, interaction with many common medicinal products that are substrates of enzymes or transporters is expected. The reduction in plasma concentrations can be substantial, and lead to lost or reduced clinical effect. There is also a risk of increased formation of active metabolites. Enzymes that may be induced include CYP3A in the liver and gut, CYP2B6, CYP2C9, CYP2C19 and uridine 5'-diphospho-glucuronosyltransferase (UGTs - glucuronide conjugating enzymes). The transport protein P-gp may also be induced, and probably other transporters as well, e.g. multidrug resistance-associated protein 2 (MRP2), breast cancer resistant protein (BCRP) and the organic anion transporting polypeptide 1B1 (OATP1B1).

*In vivo* studies have shown that enzalutamide is a strong inducer of CYP3A4 and a moderate inducer of CYP2C9 and CYP2C19. Co-administration of enzalutamide (160 mg once daily) with single oral doses of sensitive CYP substrates in prostate cancer patients resulted in an 86% decrease in the AUC of midazolam (CYP3A4

substrate), a 56% decrease in the AUC of S-warfarin (CYP2C9 substrate), and a 70% decrease in the AUC of omeprazole (CYP2C19 substrate). UGT1A1 may have been induced as well.

Interactions with certain medicinal products that are eliminated through metabolism or active transport are expected. If their therapeutic effect is of large importance to the patient, and dose adjustments are not easily performed based on monitoring of efficacy or plasma concentrations, these medicinal products are to be avoided or used with caution.

**The risk for liver injury after paracetamol administration is suspected to be higher in patients concomitantly treated with enzyme inducers.**

Groups of medicinal products that can be affected include, but are not limited to:

- Analgesics (e.g. fentanyl, tramadol)
- Antibiotics (e.g. clarithromycin, doxycycline)
- Anticancer agents (e.g. cabazitaxel)
- Anticoagulants (e.g. warfarin)
- Antiepileptics (e.g. carbamazepine, clonazepam, phenytoin, primidone, valproic acid)
- Antipsychotics (e.g. haloperidol)
- Beta-blockers (e.g. bisoprolol, propranolol)
- Calcium channel blockers (e.g. diltiazem, felodipine, nicardipine, nifedipine, verapamil)
- Cardiac glycosides (e.g. digoxin)
- Corticosteroids (e.g. dexamethasone, prednisolone)
- HIV antivirals (e.g. indinavir, ritonavir)
- Hypnotics (e.g. diazepam, midazolam, zolpidem)
- Immune modulating agents (e.g. cyclosporine, tacrolimus)
- Statins metabolised by CYP3A4 (e.g. atorvastatin, simvastatin)
- Thyroid agents (e.g. levothyroxine)

The full induction potential of enzalutamide may not occur until approximately 1 month after the start of treatment, when steady-state plasma concentrations of enzalutamide are reached, although some induction effects may be apparent earlier. Patients taking drugs that are substrates of CYP2B6, CYP3A4, CYP2C9, CYP2C19 or UGT1A1 should be evaluated for possible loss of pharmacological effects (or increase in effects in cases where active metabolites are formed) during the first month of XTANDI treatment and dose adjustment should be considered as appropriate. In consideration of the long half-life of enzalutamide (5.8 days, see **Further Information:** Pharmacokinetics), effects on enzymes may persist for one month or longer after stopping XTANDI. A gradual dose reduction of the concomitant medicinal product may be necessary when stopping XTANDI treatment.

### *Warfarin and coumarin-like anticoagulants*

Co-administration with warfarin and coumarin-like anticoagulants should be avoided. If XTANDI is co-administered with an anticoagulant metabolised by CYP2C9 (such as warfarin), additional INR monitoring should be conducted.

### *CYP1A2, and CYP2C8 substrates*

Enzalutamide (160 mg once daily) did not cause a clinically relevant change in the AUC or  $C_{max}$  of caffeine (CYP1A2 substrate), pioglitazone (CYP2C8 substrate). No dose adjustment is indicated when a CYP1A2 or CYP2C8 substrate is co-administered with XTANDI.

### *P-gp substrates*

*In vitro* data indicate that enzalutamide is not a substrate for, but may be an inhibitor of the efflux transporter P-gp. The effect of enzalutamide on P-gp substrates has not been evaluated *in vivo*; however, under conditions of clinical use, enzalutamide may be an inducer of P-gp via activation of the nuclear pregnane receptor (PXR). Medicinal products with a narrow therapeutic range that are substrates for P-gp (e.g. colchicine, dabigatran etexilate, digoxin) should be used with caution when administered concomitantly with XTANDI and may require dose adjustment to maintain optimal plasma concentrations.

### *BCRP, MRP2, OAT1, OAT3, OATP1B3, OCT1 and OCT2 substrates*

Based on *in vitro* data, inhibition of BCRP and MRP2 (in the intestine), as well as organic anion transporter 3 (OAT3), OATP1B1, and organic cation transporter 1 (OCT1) (systemically) cannot be excluded. Theoretically, induction of OAT3, OATP1B1, OCT1, BCRP and MRP2 is also possible, and the net effect is presently unknown. The effects of enzalutamide on these transporters have not been evaluated *in vivo*. *In vitro* data indicate that enzalutamide and its major metabolites do not inhibit the following transporters at clinically relevant concentrations: OAT1, OATP1B3, or OCT2.

### Effect of Food on XTANDI Exposures

Food has no clinically significant effect on the extent of exposure to XTANDI. In clinical trials, XTANDI was administered without regard to food.

### **Overdose**

There is no antidote for XTANDI. In the event of an overdose, treatment with XTANDI should be stopped and general supportive measures initiated taking into consideration the half-life of 5.8 days. Patients may be at increased risk of seizures following an overdose.

For information on the management of overdose, contact the New Zealand National Poisons Centre (0800 POISON or 0800 764 766).

## Further Information

### Actions

Enzalutamide is an androgen receptor signalling inhibitor that blocks the androgen signalling pathway. Enzalutamide competitively inhibits binding of androgens to androgen receptors, and consequently inhibits the nuclear translocation of these receptors and inhibits the binding of androgen receptor to DNA. *In vitro*, enzalutamide treatment decreased proliferation and induced prostate cancer cell death. Decreased tumour growth was seen in a mouse prostate cancer xenograft model. In preclinical studies enzalutamide lacked androgen receptor agonist activity against several prostate cancer cell lines. The active metabolite, N-desmethyl enzalutamide, exhibited similar *in vitro* activity to enzalutamide in the inhibition of testosterone binding to the androgen receptor.

### Pharmacokinetics

The pharmacokinetics of enzalutamide have been evaluated in prostate cancer patients and in healthy male subjects. The mean terminal half-life ( $t_{1/2}$ ) for enzalutamide in patients after a single oral dose is 5.8 days (range 2.8 to 10.2 days), and steady-state is achieved in approximately one month. With daily oral administration, enzalutamide accumulates approximately 8.3-fold relative to a single dose. Daily fluctuations in plasma concentrations are low (peak-to-trough ratio of 1.25). Clearance of enzalutamide is primarily via hepatic metabolism, producing an active metabolite that circulates at approximately the same plasma concentration as enzalutamide.

### *Absorption*

Maximum plasma concentrations ( $C_{max}$ ) of enzalutamide in patients are observed 1 to 2 hours after administration. Based on a mass balance study in humans, oral absorption of enzalutamide is estimated to be at least 84.2%. Enzalutamide is not a substrate of the efflux transporters P-gp or BCRP. At steady-state, the mean  $C_{max}$  values for enzalutamide and its active metabolite are 16.6 µg/mL (23% coefficient of variation [CV]) and 12.7 µg/mL (30% CV), respectively.

Food has no clinically significant effect on the extent of absorption. In clinical trials, XTANDI was administered without regard to food.

### *Distribution*

The mean apparent volume of distribution (V/F) of enzalutamide in patients after a single oral dose is 110 L (29% CV). The volume of distribution of enzalutamide is greater than the volume of total body water, indicative of extensive extravascular distribution. Studies in rodents indicate that enzalutamide and its active metabolite can cross the blood brain barrier.

Enzalutamide is 97% to 98% bound to plasma proteins, primarily albumin. The active metabolite is 95% bound to plasma proteins. There was no protein binding

displacement between enzalutamide and other highly bound drugs (warfarin, ibuprofen and salicylic acid *in vitro*).

### *Metabolism*

Enzalutamide is extensively metabolised. There are two major metabolites in human plasma: N-desmethyl enzalutamide (active) and a carboxylic acid derivative (inactive). Enzalutamide is metabolised by CYP2C8 and to a lesser extent by CYP3A4/5 (see **Interactions**), both of which play a role in the formation of the active metabolite. N-desmethyl enzalutamide was not metabolized by CYPs *in vitro*.

Under conditions of clinical use, enzalutamide is a strong inducer of CYP3A4, a moderate inducer of CYP2C9 and CYP2C19, and has no clinically relevant effect on CYP2C8 (see **Interactions**).

### *Excretion*

The mean apparent clearance (CL/F) of enzalutamide in patients ranges from 0.520 and 0.564 L/h.

Following oral administration of <sup>14</sup>C-enzalutamide, 84.6% of the radioactivity is recovered by 77 days post dose: 71.0% is recovered in urine (primarily as the inactive metabolite, with trace amounts of enzalutamide and the active metabolite), and 13.6% is recovered in faeces (0.39% of dose as unchanged enzalutamide).

### *Linearity*

No major deviations from dose proportionality are observed over the dose range 40 to 160 mg. The steady-state  $C_{min}$  values of enzalutamide and the active metabolite in individual patients remained constant during more than one year of chronic therapy, demonstrating time-linear pharmacokinetics once steady-state is achieved.

## Pharmacokinetic Characteristics in Special Populations

*Patients with hepatic impairment:* The pharmacokinetics of enzalutamide were examined in subjects with baseline mild (N = 6), moderate (N = 8) or severe (N = 8) hepatic impairment (Child-Pugh Class A, B and C, respectively) and in 22 matched control subjects with normal hepatic function. Following a single oral 160 mg dose of enzalutamide, the AUC and  $C_{max}$  for enzalutamide in subjects with mild impairment increased by 5% and 24%, respectively, the AUC and  $C_{max}$  of enzalutamide in subjects with moderate impairment increased by 29% and decreased by 11%, respectively and the AUC and  $C_{max}$  of enzalutamide in subjects with severe impairment increased by 5% and decreased by 41% respectively compared to healthy control subjects. For the sum of unbound enzalutamide plus the unbound active metabolite, the AUC and  $C_{max}$  in subjects with mild impairment increased by 14% and 19%, respectively, and the AUC and  $C_{max}$  in subjects with moderate impairment increased by 14% and decreased by 17% respectively and the AUC  $C_{max}$  of enzalutamide in subjects with severe

impairment increased by 34% and decreased by 27% respectively compared to healthy control subjects.

*Patients with renal impairment:* No formal renal impairment study for enzalutamide has been completed. Patients with serum creatinine > 177 µmol/L (2 mg/dL) were excluded from clinical trials. Based on a population pharmacokinetic analysis, no dose adjustment is necessary for patients with calculated creatinine clearance (CrCL) values ≥ 30 mL/min (estimated by the Cockcroft and Gault formula). Enzalutamide has not been evaluated in patients with severe renal impairment (CrCL < 30 mL/min) or end-stage renal disease, and caution is advised when treating these patients. It is unlikely that enzalutamide will be significantly removed by intermittent haemodialysis or continuous ambulatory peritoneal dialysis.

*Elderly:* No clinically relevant effect of age on enzalutamide pharmacokinetics was seen in the population pharmacokinetic analysis.

*Paediatric use:* Safety and effectiveness of enzalutamide in paediatric patients have not been established.

*Gender and race:* The effect of gender on the pharmacokinetics of enzalutamide has not been evaluated. Most patients in the clinical trials (> 92%) were Caucasian. There are insufficient data to evaluate potential differences in the pharmacokinetics of enzalutamide in other races.

## Other

### *Clinical Trials*

Efficacy of enzalutamide was established in two randomised placebo-controlled multicentre phase 3 clinical studies [CRPC2 (AFFIRM), MDV3100-03 (PREVAIL)] of patients with progressive metastatic prostate cancer who had failed androgen deprivation therapy [luteinising hormone-releasing hormone (LHRH) analogue or after bilateral orchiectomy]. The PREVAIL study controlled chemotherapy-naïve patients; whereas the AFFIRM study enrolled patients who had received prior docetaxel. All patients continued on a LHRH analogue or had prior bilateral orchiectomy. In the active treatment arm, XTANDI was administered orally at a dose of 160 mg daily. In both clinical trials, patients received placebo in the control arm and patients were allowed, but not required, to take prednisone (maximum daily dose allowed was 10 mg prednisone or equivalent).

Changes in prostate specific antigen (PSA) serum concentration independently do not always predict clinical benefit. Therefore, in both studies it was recommended that patients be maintained on their study treatments until discontinuation criteria were met as specified below for each study.

### **MDV3100-03 (PREVAIL) study (chemotherapy-naive patients)**

A total of 1717 asymptomatic or mildly symptomatic chemotherapy-naive patients were randomized 1:1 to receive either enzalutamide orally at a dose of 160 mg once daily (N

= 872) or placebo orally once daily (N = 845). Patients with visceral disease, patients with a history of mild to moderate heart failure (NYHA Class 1 or 2), and patients taking medications associated with lowering the seizure threshold were allowed. Patients with a previous history of seizure or a condition that might predispose to seizure and patients with moderate or severe pain from prostate cancer were excluded. Study treatment continued until disease progression (evidence of radiographic progression, a skeletal related event, or clinical progression) and the initiation of either a cytotoxic chemotherapy or an investigational agent, or until unacceptable toxicity.

Patient demographics and baseline disease characteristics were balanced between the treatment arms. The median age was 71 years (range 42-93) and the racial distribution was 77% Caucasian, 10% Asian, 2% Black and 11% other or unknown races. Sixty-eight percent (68%) of patients had an ECOG performance status score of 0 and 32% of patients had ECOG performance status 1. Baseline pain assessment was 0-1 (asymptomatic) in 67% of patients and 2-3 (mildly symptomatic) in 32% of patients as defined by the Brief Pain Inventory Short Form (worst pain over past 24 hours on a scale of 0 to 10). Approximately 45% of patients had measurable soft tissue disease at study entry, and 12% of patients had visceral (lung and/or liver) metastases.

Co-primary efficacy endpoints were overall survival and radiographic progression-free survival (rPFS). In addition to the co-primary endpoints, benefit was also assessed using time to initiation of cytotoxic chemotherapy, best overall soft tissue response, time to first skeletal-related event, PSA response ( $\geq 50\%$  decrease from baseline), time to PSA progression, and time to FACT-P total score degradation.

Radiographic progression was assessed with the use of sequential imaging studies as defined by Prostate Cancer Clinical Trials Working Group 2 (PCWG2) criteria (for bone lesions) and/or Response Evaluation Criteria in Solid Tumours (RECIST v 1.1) criteria (for soft tissue lesions). Analysis of rPFS utilised centrally-reviewed radiographic assessment of progression.

At the pre-specified interim analysis for overall survival, although the overall survival data may be immature, treatment with enzalutamide demonstrated a statistically significant improvement in overall survival compared to treatment with placebo with a 29% reduction in risk of death [HR=0.706, (95% CI: 0.596; 0.837),  $p < 0.0001$ ] (Table 3). Of note, 40.4% of enzalutamide-treated patients and 70.5% of placebo-treated patients received subsequent therapies with a demonstrated survival benefit.

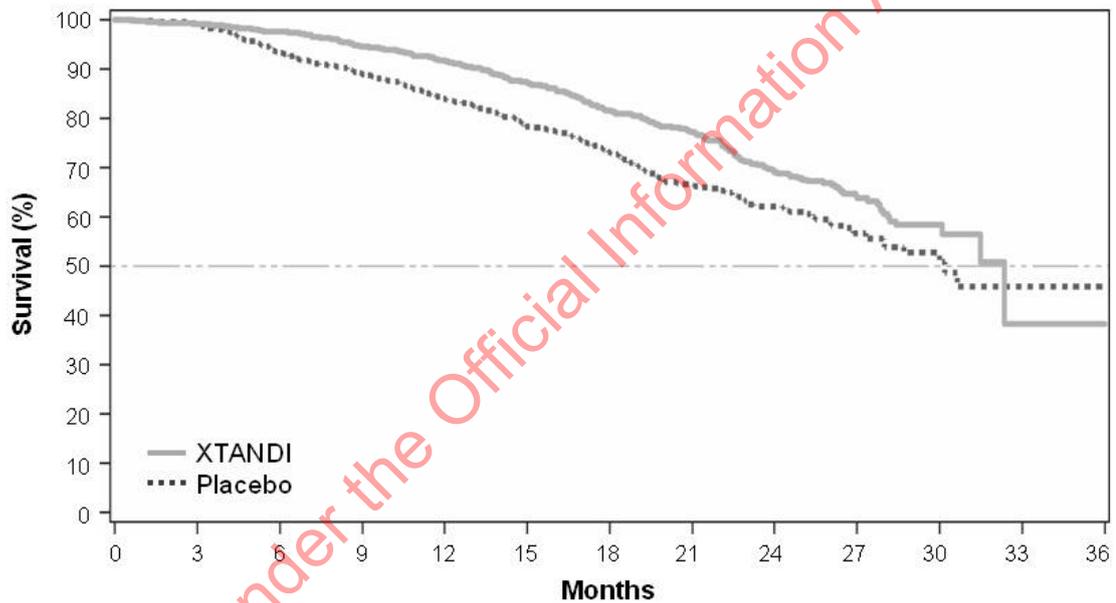

**Table 3: Overall Survival of Patients Treated with Either Enzalutamide or Placebo in the PREVAIL Study (Intent-to-Treat Analysis)**

	<b>Enzalutamide (N = 872)</b>	<b>Placebo (N = 845)</b>
Pre-specified interim analysis		
Number of deaths (%)	241 (27.6%)	299 (35.4%)
Estimated median, months (95% CI)	32.4 (30.1, NR)	30.2 (28.0, NR)
P-value <sup>a</sup>	< 0.0001	
Hazard ratio (95% CI) <sup>b</sup>	0.71 (0.60, 0.84)	

<sup>a</sup>) P-value is derived from an unstratified log-rank test

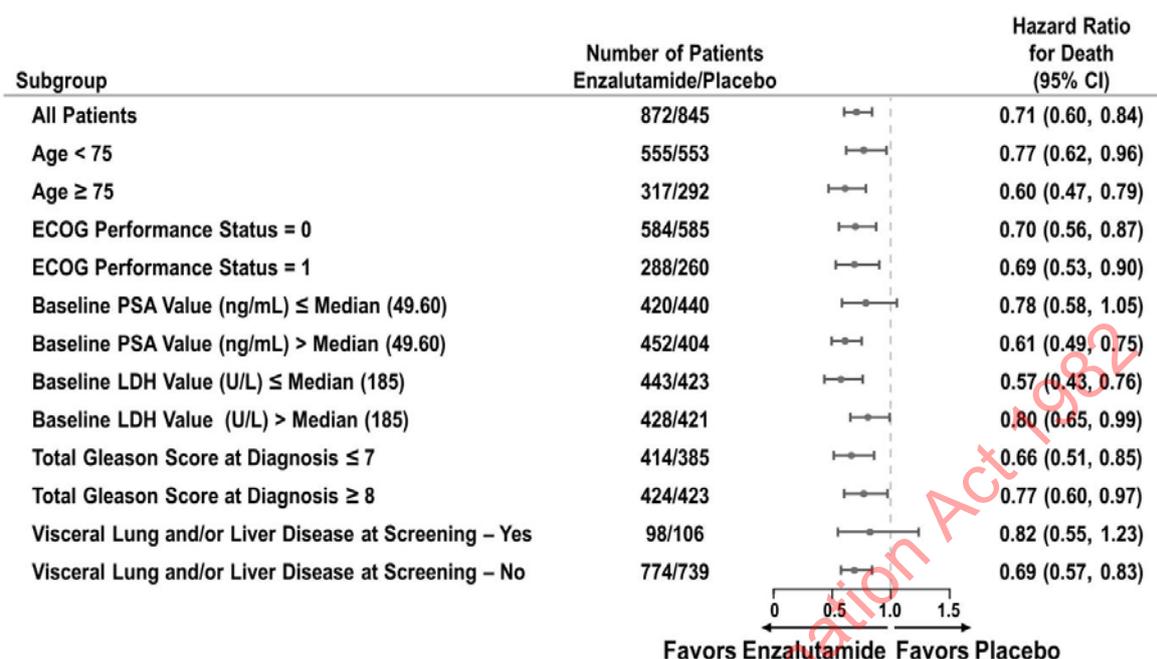

<sup>b</sup>) Hazard Ratio is derived from an unstratified proportional hazards model. Hazard ratio <1 favours enzalutamide  
NR, not reached.

**Figure 1: Kaplan-Meier Overall Survival Curves Based on Pre-specified Interim Survival Analysis in the PREVAIL Study (Intent-to-Treat Analysis)**

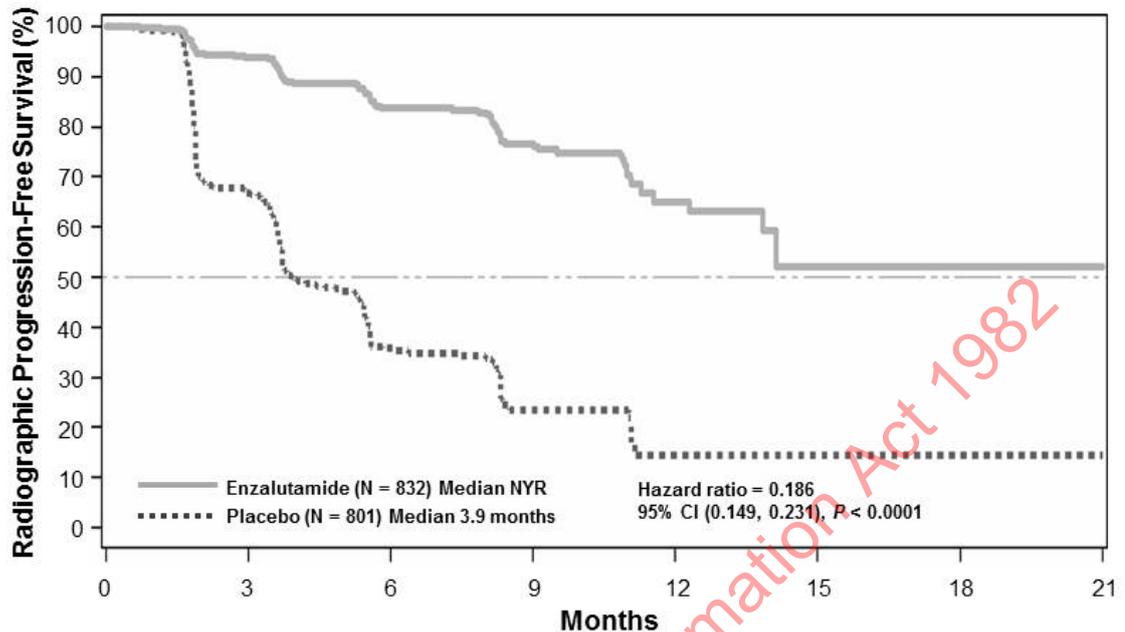

Patients at risk		0	3	6	9	12	15	18	21	24	27	30	33	36
XTANDI	872	863	850	824	797	745	566	395	244	128	33	2	0	0
Placebo	845	835	781	744	701	644	484	328	213	102	27	2	0	0

**Figure 2: Overall Survival by Subgroup: Hazard Ratio and 95% Confidence Interval in the PREVAIL Study (Intent-to-Treat Analysis)**

At the pre-specified rPFS analysis, a statistically significant improvement was demonstrated between the treatment groups with an 81.4% reduction in risk of radiographic progression or death [HR = 0.186 (95% CI: 0.149, 0.231),  $p < 0.0001$ ]. One hundred and eighteen (14%) enzalutamide-treated patients and 321 (40%) of placebo-treated patients had an event. The median rPFS was not reached (95% CI: 13.8, not reached) in the enzalutamide-treated group and was 3.9 months (95% CI: 3.7, 5.4) in the placebo-treated group (Figure 3). Consistent rPFS benefit was observed across all pre-specified patient subgroups (e.g., age, baseline ECOG performance, baseline PSA and LDH, Gleason score at diagnosis, and visceral disease at screening). A pre-specified follow-up rPFS analysis based on the investigator assessment of radiographic progression demonstrated a statistically significant improvement between the treatment groups with a 69.3% reduction in risk of radiographic progression or death [HR = 0.307 (95% CI: 0.267, 0.353),  $p < 0.0001$ ]. The median rPFS was 19.7 months in the enzalutamide group and 5.4 months in the placebo group.

**Figure 3: Kaplan-Meier Curves of Radiographic Progression-Free Survival in the PREVAIL Study (Intent-to-Treat Analysis)**

**Patients at risk**

Enzalutamide	832	514	256	128	34	5	1	0
Placebo	801	305	79	20	5	0	0	0

At the time of the primary analysis there were 1633 patients randomised.

In addition to the co-primary efficacy endpoints, statistically significant improvements were also demonstrated in the following prospectively defined endpoints.

The median time to initiation of cytotoxic chemotherapy was 28.0 months for patients receiving enzalutamide and 10.8 months for patients receiving placebo (HR=0.350, 95% CI: [0.303, 0.403],  $p < 0.0001$ ). The proportion of enzalutamide-treated patients with measurable disease at baseline who had an objective soft tissue response was 58.8% (95% CI: 53.8, 63.7) compared with 5.0% (95% CI: 3.0, 7.7) of patients receiving placebo. The absolute difference in objective soft tissue response between enzalutamide and placebo arms was 53.9% (95% CI: 48.5%, 59.1%,  $p < 0.0001$ ). Complete responses were reported in 19.7% of enzalutamide-treated patients compared with 1.0% of placebo-treated patients, and partial responses were reported in 39.1% of enzalutamide-treated patients versus 3.9% of placebo-treated patients.

Enzalutamide significantly decreased the risk of the first skeletal-related event by 27% [HR=0.526, (95% CI: 0.421, 0.656),  $p < 0.0001$ ], 21.6% of enzalutamide-treated patients reported a skeletal-related event versus 18.5% of placebo-treated patients, an absolute difference of 3.1% events. A skeletal-related event was defined as radiation therapy or surgery to bone for prostate cancer, pathologic bone fracture, spinal cord compression, or change of antineoplastic therapy to treat bone pain.

The median time to PSA progression per PCWG2 criteria was 11.2 months for patients treated with enzalutamide and 2.8 months for patients who received placebo [HR=0.169, (95% CI: 0.147, 0.195),  $p < 0.0001$ ].

Treatment with enzalutamide decreased the risk of FACT-P degradation by 37.5% compared with placebo ( $p < 0.001$ ). The median time to degradation in FACT-P was 11.3 months in the enzalutamide group and 5.6 months in the placebo group.

### **CRPC2 (AFFIRM) study (patients who previously received chemotherapy)**

The efficacy and safety of XTANDI in patients with metastatic castration-resistant prostate cancer who had received docetaxel and were using a LHRH analogue or had undergone orchiectomy were assessed in a randomised, placebo-controlled, multicentre phase 3 clinical trial (AFFIRM). A total of 1199 patients were randomised 2:1 to receive either XTANDI orally at a dose of 160 mg once daily (N = 800) or placebo once daily (N = 399). Patients were allowed but not required to take prednisone (maximum daily dose allowed was 10 mg prednisone or equivalent). Patients randomised to either arm were to continue treatment until disease progression (defined as confirmed radiographic progression or the occurrence of a skeletal-related event) and initiation of new systemic antineoplastic treatment, unacceptable toxicity, or withdrawal. Following progression, 41% of study drug arm and 61.7% of placebo arm received  $\geq 1$  further systemic treatments therefore the observed survival data and Kaplan-Meier curve reflect a median duration of treatment of 8 months of enzalutamide vs 3 months of placebo followed by additional treatments.

The following patient demographics and baseline disease characteristics were balanced between the treatment arms. The median age was 69 years (range 41-92) and the racial distribution was 92.7% Caucasian, 3.9% Black, 1.1% Asian, and 2.1% Other. The ECOG performance score was 0-1 in 91.5% of patients and 2 in 8.5% of patients; 28.4% had a mean Brief Pain Inventory score of  $\geq 4$  (mean of patient's reported worst pain over the previous 24 hours calculated for seven days prior to randomisation). Most (91.2%) patients had metastases in bone and 23.2% had visceral lung and/or liver involvement. At study entry, 41% of randomised patients had PSA progression only, whereas 59% of patients had radiographic progression. 51% of patients were on bisphosphonates at baseline.

The AFFIRM study excluded patients with medical conditions that may predispose them to seizures (see **Adverse Effects**) and medications known to decrease the seizure threshold, as well as clinically significant cardiovascular disease such as uncontrolled hypertension, recent history of myocardial infarction or unstable angina, New York Heart Association class III or IV heart failure (unless ejection fraction was  $\geq 45\%$ ), clinically significant ventricular arrhythmias or AV block (without permanent pacemaker).

The protocol pre-specified interim analysis after 520 deaths showed a statistically significant superiority in overall survival in patients treated with XTANDI compared to placebo (Table 4 and Figure 4).

**Table 4: Overall Survival of Patients Treated with Either XTANDI or Placebo in the AFFIRM Study (intent-to-treat analysis)**

	<b>XTANDI (N = 800)</b>	<b>Placebo (N = 399)</b>
Deaths (%)	308 (38.5%)	212 (53.1%)
Median survival (months) (95% CI)	18.4 (17.3, NR)	13.6 (11.3, 15.8)
P-value <sup>a</sup>	< 0.0001	
Hazard ratio (95% CI) <sup>b</sup>	0.631 (0.529, 0.752)	

a Median duration of treatment of 8 months of enzalutamide vs 3 months of placebo followed by additional treatments.

b P-value is derived from a log-rank test stratified by ECOG performance status score (0-1 vs. 2) and mean pain score (< 4 vs. ≥ 4).

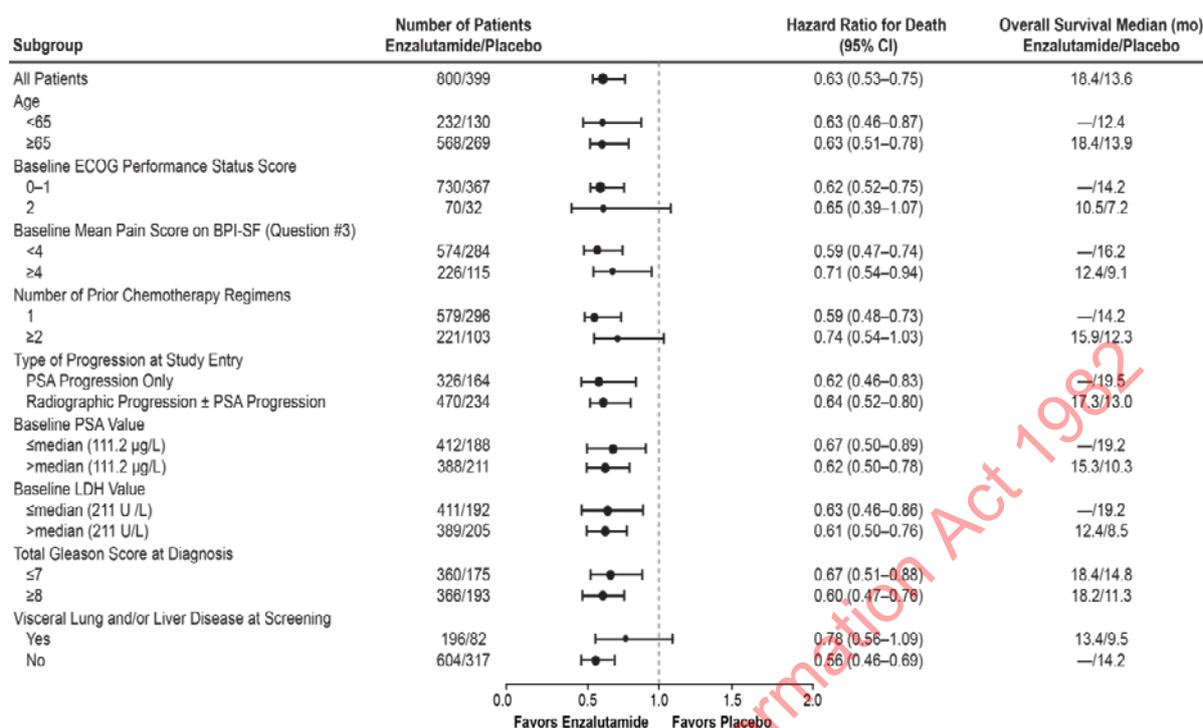

c Hazard ratio is derived from a stratified proportional hazards model. Hazard ratio <1 favours XTANDI.

**Figure 4: Kaplan-Meier Overall Survival Curves in the AFFIRM Study (intent-to-treat analysis)**

Subgroup survival analysis showed a consistent survival benefit for treatment with XTANDI (see Figure 5).

**Figure 5: Overall Survival by Subgroup in the AFFIRM Study – Hazard Ratio and 95% Confidence Interval**

ECOG: Eastern Cooperative Oncology Group; BPI-SF: Brief Pain Inventory-Short Form; PSA: Prostate Specific Antigen

In addition to the observed improvement in overall survival, key secondary endpoints (radiographic progression-free survival, and time to first skeletal-related event) favoured XTANDI and were statistically significant after adjusting for multiple testing.

Radiographic progression-free survival as assessed by the investigator using RECIST v1.1 for soft tissue and appearance of 2 or more bone lesions in bone scan was 8.3 months for patients treated with XTANDI and 2.9 months for patients who received placebo (HR = 0.404, 95% CI: [0.350, 0.466]);  $p < 0.0001$ ). The analysis involved 216 deaths without documented progression and 645 documented progression events, of which 303 (47%) were due to soft tissue progression, 268 (42%) were due to bone lesion progression and 74 (11%) were due to both soft tissue and bone lesions.

The median time to first skeletal-related event was 16.7 months for patients treated with XTANDI and 13.3 months for patients who received placebo (HR = 0.688, 95% CI: [0.566, 0.835];  $p < 0.0001$ ). A skeletal-related event was defined as radiation therapy or surgery to bone, pathologic bone fracture, spinal cord compression, or change of antineoplastic therapy to treat bone pain.

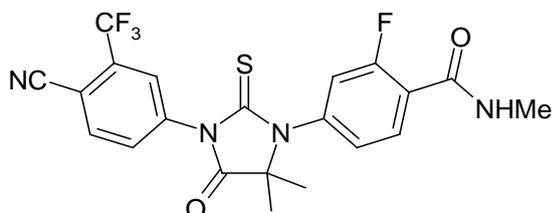

The efficacy of enzalutamide in patients who have previously received abiraterone acetate has not been studied.

### Older people

Of the 1671 patients in the phase 3 trials who received enzalutamide, 1261 patients (75.5%) were 65 years and over and 516 patients (30.9%) were 75 years and over. No overall differences in safety or effectiveness were observed between these older patients and younger patients. The incidence of serious adverse events, fatal adverse

events and adverse events leading to discontinuation was higher in older patients ( $\geq 75$  years). For patients  $\geq 75$  years, one of these adverse events was reported in 50.5% of patients in the enzalutamide arm and 50.0% in the placebo arm. For patients  $< 75$  years, one of these adverse events was reported in 37.0% of patients in the enzalutamide arm and 29.5% of patients in the placebo arm.

### Chemical Structure

Molecular formula:  $C_{21}H_{16}F_4N_4O_2S$

CAS registry number: 915087-33-1

*Chemical name:* 4-{3-[4-cyano-3-(trifluoromethyl)phenyl]-5,5dimethyl-4-oxo-2-thioxoimidazolidin-1-yl}-2-fluoro-N-methylbenzamide

Enzalutamide is a white crystalline non-hygroscopic solid. It is practically insoluble in water.

### List of Excipients

XTANDI capsules contain the following inactive ingredients: caprylocaproyl macrogolglycerides, butylated hydroxyanisole, butylated hydroxytoluene, gelatin, sorbitol, sorbitan, glycerol, purified water, titanium dioxide, black iron oxide and polyvinyl acetate phthalate.

### Pharmaceutical Precautions

#### Shelf-life

3 years

#### Storage Condition

Store below 25°C

### Package Quantities

XTANDI capsules are supplied in a cardboard wallet incorporating a PVC/PCTFE/aluminium blister of 28 soft capsules. Each carton contains 4 wallets (112 soft capsules).
